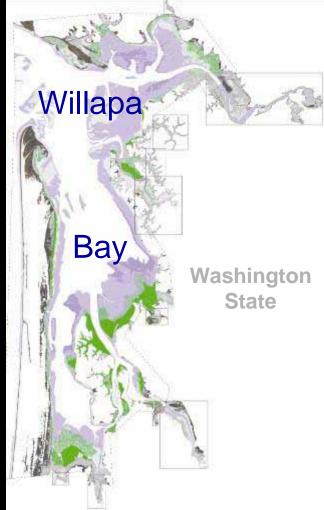

Mapping Predicted Tidal Exposure Durations Using a MLLW-Referenced LiDAR Terrain Model

for Management of *Spartina alterniflora* in Willapa Bay, Washington

Meeting the Challenge: Invasive Plants in PNW Ecosystems September 20, 2006

Invasive Spartina

Nearly 1/3 of all viable fish and wildlife tide-flat habitat in Willapa Bay is infested with *Spartina alterniflora*.

The bay supports shellfish and fin fisheries as well as the Willapa National Wildlife Refuge.

At risk: biological diversity, the local economy...

Methods used to control the infestation

Chemical

Mechanical

Biological

We use GIS for:

Bay-wide planning

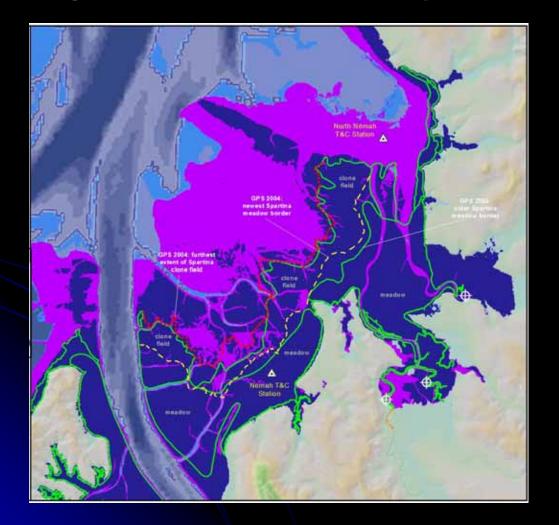

Site-specific planning

Communication among stakeholders And the public

Providing spatially explicit tide prediction maps for chemical applications

Showing when, where and for how long plants will be exposed for treatments

Minimize treatment impact

Optimize treatment efficacy

Determining appropriate areas and times for chemical applications

Environmental Factors:

Plant growth

Properties of Chemicals

Tides

Plant Growth and Chemical Properties

Plant Growth

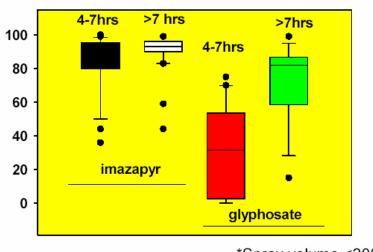

Early season

plants very short, treatment of plant low on tideflats more difficult

Late season

plants much taller, treatment of plants low on tideflats much easier

*Spray volume <200 l/ha

Efficacy comparison for 1.68 kg/ha imazapyr and 8.4 kg/ha glyphosate as a function of dry times*

Research by Dr. Kim Patten, WSU Long Beach

Chemical Properties

Different chemicals need different minimum exposure times

> Leaves must be *dry* a certain amount of time to give the herbicide time to affect the plant

The Tides

No fixed patterns

• Treatable areas change daily

Tide timing varies across the bay

 Timing varies by approximately 1 hour depending on distance from the mouth of the bay

Water levels vary across the bay

- Levels can vary by more than 3 feet at any given time
- Levels become more extreme in channel / sloughs as well as areas farther from the mouth

Preparation for Mapping

Understanding the Environment

Plant growth Properties of Chemicals

Tides

Available Data

LiDAR Terrain Data

NOAA NOS Tide Prediction Data

Using a Common Elevation Reference

Different terrain data use different elevation datums

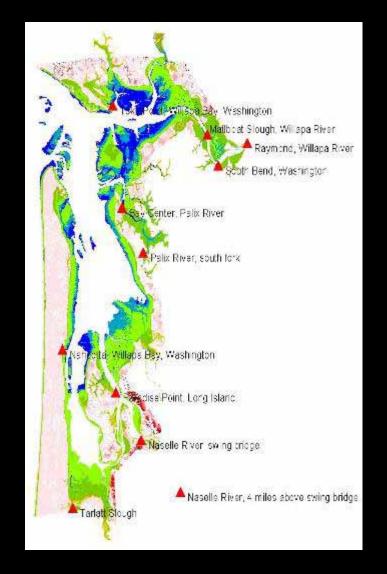

• LiDAR derived terrain model elevation datum is NAVD88

• NOAA NOS Tide Prediction stations datum is MLLW (Mean Lower Lowest Water)

The Solution

 Adjust terrain model elevations to MLLW to match the tide prediction data

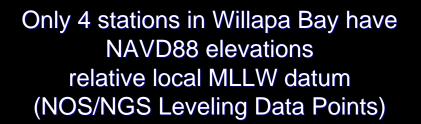

We can then "flood" the terrain model using "water" whose surface is interpolated from NOAA NOS tide prediction stations.

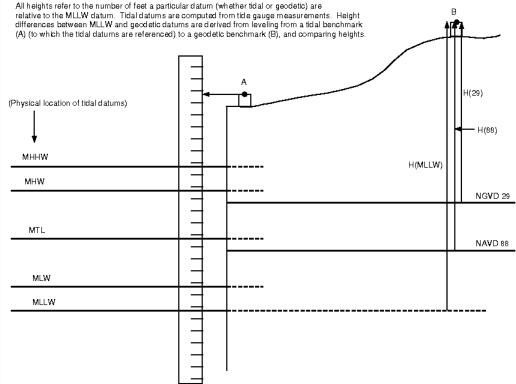

Referencing the Terrain Data

Tide Datums vary from location to location

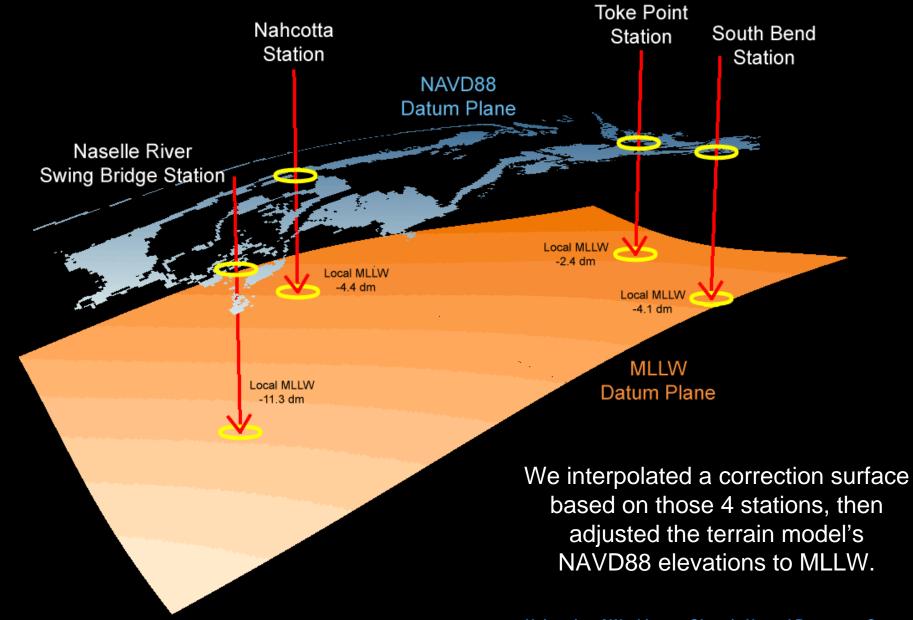

The NWO 68 and the NUVO 29 elevations related to MLLM were computed from Bench Mark, TIDRL 2, at the station.

Disployed lidel delaws are Nean Higher High Maler(M986), Mean High Water (980), Mean Tide Level(MTL), Mean Low Water(9834), and Mean Lower Low Hater(MLLM) The NWHO 88 and the NOVO 29 elevations related to MLDA were computed from Dench Mark, TIDAL 5, at the station.

Disployed Tifel deforms are Mean Fligher High Holer(MRHAD), Nean High Water (MHA), Mean Tife Level(MTL), Mean Low Nater(MLM), and Mean Lower Low Mater(MLM)

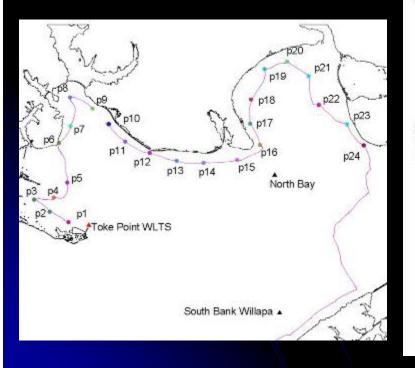

Referencing the Base Terrain Data

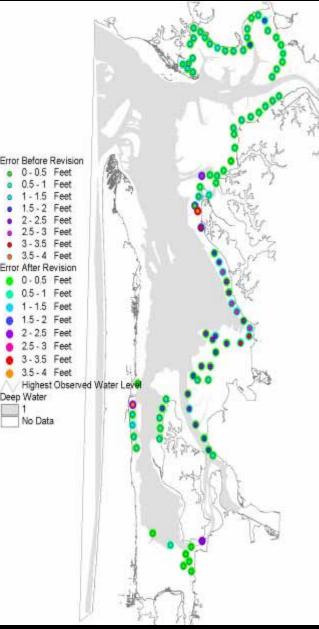

Validating the MLLW-Referenced Terrain Model

1. Capture a water line with a time and location at each point using GPS

Each point on the water line is a point where the water's surface intersects the terrain.

2. Compare the terrain model at each location with a surface representing the tide at each time. Any difference is an error.

3. We assign this error value to each GPS point, then interpolate an 'error surface' and adjust the terrain model.

Validating the MLLW-Referenced Terrain Model

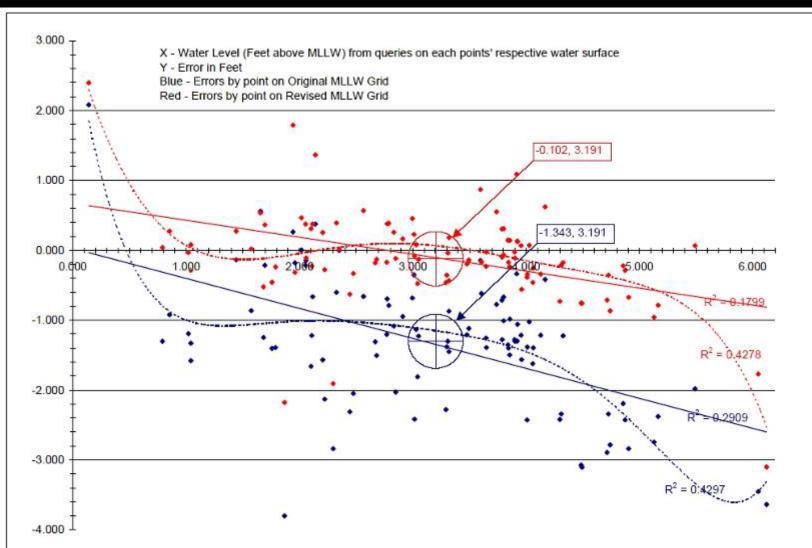

Figure 9. Error clouds before (blue) and after (red) corrections

The 6^{th} order regression curves and linear regressions were done using Excel, the software used for creating these xy scatter plots. They x axis is the water level at each point, obtained by querying that point's water "snapshot" and remains the same for both error clouds. The y-axis is the difference between that water level and the respective terrain models.

Gathering Tide Prediction Data

* Data on the Cheap

We needed high temporal resolution prediction data for as many locations as we could get. We evaluated different free and for-purchase software packages. Of all the tide prediction programs offered, we found Nobeltec's Tides & Currents (T&C) software to be most consistent with NOAA's tide predictions.

* Tide Station Updates

Last year, NOAA updated to the 1983-2001 tidal Epoch from the 1960-1978 Epoch used in previous years. Not all stations were updated. In addition, they dropped 1 of 12 stations that provides hourly tide predictions. As of April 1, their new web page is http://www.tidesandcurrents.noaa.gov

* Whose Data Is Best?

To save time and money, we adapted NOAA CO-OPS data as the "gold standard" for six-minute and hourly prediction data. Here is a short description of the data we work with:

<u>Type</u>	Availability	Number of Stations
Six-minute	On-the-fly	3
Hourly	Published Tables	11
Parameters	Published Tables	11

	•

How it works!

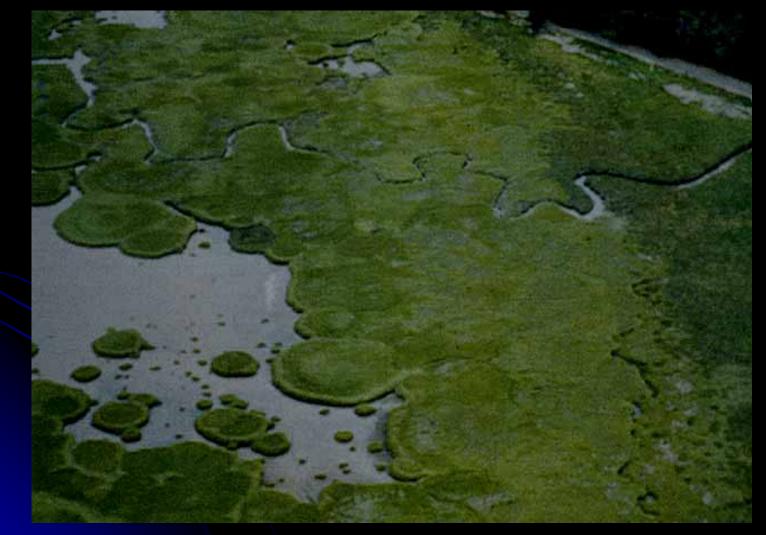

1. Start with the MLLW referenced LiDAR terrain model 2. A Spartina stem height grid is overlaid onto the terrain model

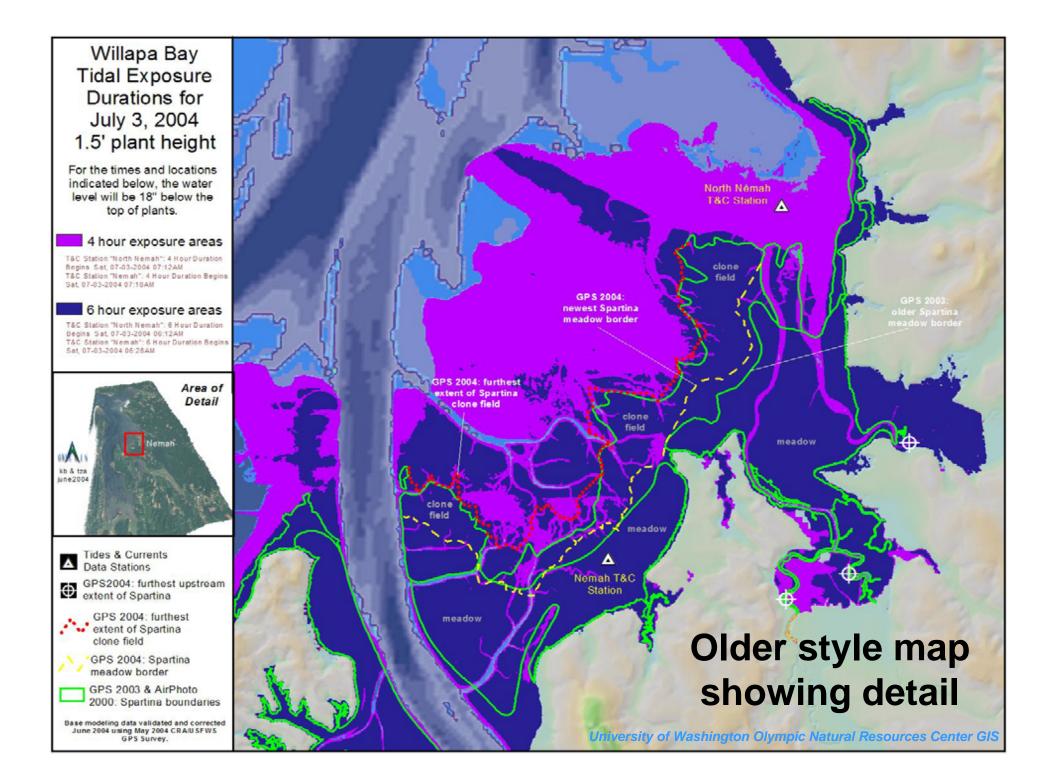

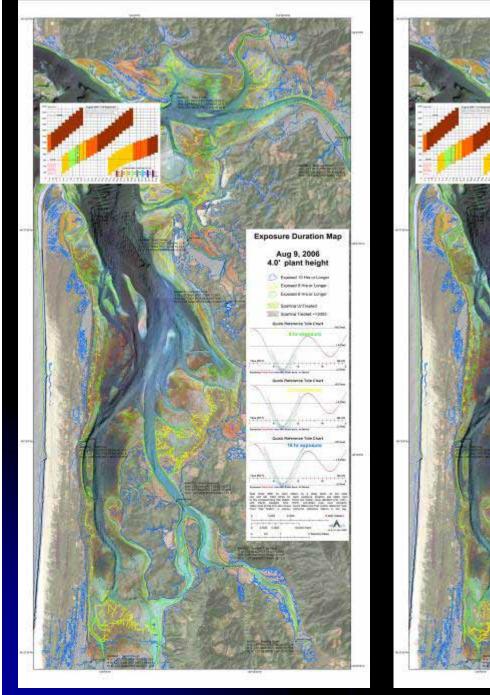

3. "Flood" the terrain model with the interpolated water surface

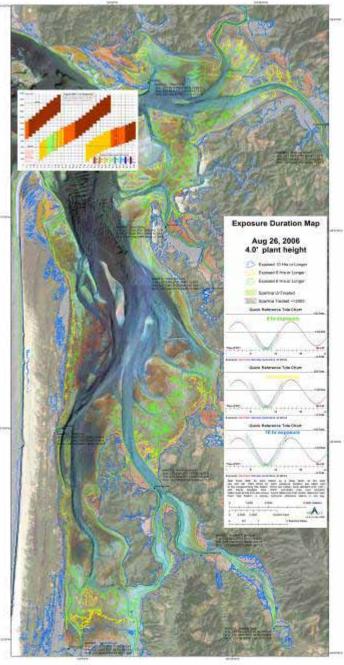

Anything 18" above the water surface is exposed and treatable for the desired duration.
